Soros language specification[1]

DRAFT, 2009-09-28[2]

László Németh (nemeth@openoffice.org)

1   Introduction

The Soros programming language is a regex based language for conversion between self-similar character sequences. A typical conversion task is the number to number name conversion, and the language is originally developed for the generalization of the BAHTTEXT spreadsheet function, a function of Microsoft Excel for number to Thai number name and currency conversion, standardized by the ECMA–376 and ISO/IEC 29 500:2008 Office Open XML format[3]. Soros language is also the intended SPELLOUT replacement of the rule based number formatter (RBNF) of IBM ICU and Unicode CLDR database.[4]

2   Syntax

A Soros program implicitly defines a single string function named $ (dollar).

2.1   Program lines

A Soros program (the function $) consists of lines of conditional commands. Lines can be separated by new line or semicolon characters. Empty lines, leading and trailing white space characters of the lines are removed by the interpreter before the program execution (see also comments).

2.2   Commands

A command has a *regex* part and a return *value* separated by the first (not quoted) white space or white space sequence:

regex value

The function $ returns with the return value of the first matched command. Without any matching the return value is the empty string.

2.3   Regex part of the command

The *regex* part is the condition of the command. The *portable* Soros *regex* is an extended regular expression (described in ISO/IEC 9945-2:1993) with a single Perl regex extension, the possible usage of the \d notation for `[:digit:]` or `[0-9]` (digits) and the \D notation for non-digits (`[^0-9]`).

---

1   Released under the Creative Commons 2.0 Attribution-NoDerivs license

2   Modifications: new Java implementation and minor fixes in Python implementation (2010-04-19). Comments about Unicode CLDR and DollarText; corrections for RuleBasedNumberFormat; BSD license for Python and Java interpreters of the appendix of the specification (2010-05-28).

3   This standard also contains an English spellout function with currency handling, see DollarText in ECMA-376, Part 4, section 2.16.4.

4   RBNF is a rule language only for numerical input. Handling currencies and their special suffixation can be quite difficult and redundant in RBNF, so RBNF database of Unicode CLDR misses currency handling.

2.3.1 Matching

The *regex* matches the input string, if and only if the matching is full matching and the implicit input boundary values meet the global input boundary criteria (see next section).

2.3.2 Global input boundary criteria

The optional regex `^` and `$` boundary notations in REGEX part of the command define global input boundary criteria. The parameter of the first call (the global input) always matches both of these conditions, but the matching of the parameter of a recursive call depends on the position of the recursive call in the return value. The interpreter adds implicit boundary data to the recursive calls. When the recursive call is there in leading position (for example the `$1` in the `$1$2$3` or the nested `$($1$2$3)` return values), the input of the recursive call inherits the leading boundary data of the recent input. When the recursive call is there in trailing position (for example the `$3` in the `$1$2$3` or `$($1$2$3)` return values), the recursive call inherits the trailing boundary data of the recent input. See also global input boundary modifiers.

2.3.3 Quoting

Regex part can contain white spaces and both parts of the Soros commands can contain leading or trailing white spaces by quoting with the optional ASCII quotation marks:

"regex with spaces" "value   "

2.4 Return value part of the command

The return value is a character sequence with optional spaces, standard regex back references, recursive calls, abbreviated recursive calls and boundary modifiers for recursive calls.

2.4.1 Back references – \1 … \9

`\1` … `\9` are back references to the parenthesized subexpressions of the *regex* part, like in the POSIX standard Unix tools, *sed* and *awk*.

2.4.2 Recursive calls – $(*param*)

The expression `$(param)` will be replaced by the result of the recursive call of the main `$` function with the parameter *param*. Nested function calls are interpreted in adequate order.

2.4.3 Abbreviated recursive calls – $1 … $9

`$1` … `$9` are abbreviated forms of the `$(\1)` … `$(\9)` recursive calls.

2.4.4 Global input boundary modifiers

Recursive calls without boundary position in the return value lose their global input boundary values. Pipe signs before or after recursive calls are boundary modifiers and declare global input boundaries within the value.

The call with empty string can differentiate the right and left boundary modifiers. The `$1|$2` is equivalent form of the `$1||$2`. The following form sets global input boundary modifier only to the second non-empty call: `$1$()|$2`.

2.5 __numbertext__

The __numbertext__ directive sets the NUMBERTEXT mode: removing left zeros from the input (also in the recursive calls) and removing leading, trailing and double spaces from the output.

Note: The left zero deletion can be implemented by adding the following (first) program line to the programs:

```
0+(0|[1-9]\d*) $1
```

2.6 Special characters

Back slash, ASCII quotion mark, dollar sign, left and right parentheses, pipe sign, hash mark, semicolon and new line characters can be added by their quoted forms and by the \n new line notation:

```
\\, \", \$, \(, \), \|, \#, \; \n
```

2.7 Comments

Hash mark signs comments (terminated by the next new line character or the end of the program):

```
# full-line comment
1 one # in-line comment
2 two # semicolons (;) are parts of the comments, too
```

3 Examples

Reverse input string (Example 1):

```
(.*)(.) \2$1
```

Add thousand separators (Example 2):

```
(\d+)(\d{3}) $1,\2
(\d+) \1
```

Number to Devanagari numeral conversion (Example 3):

```
(\d*)0    $1०
(\d*)1    $1१
(\d*)2    $1२
(\d*)3    $1३
(\d*)4    $1४
(\d*)5    $1५
(\d*)6    $1६
(\d*)7    $1७
(\d*)8    $1८
(\d*)9    $1९
```

Number to English number name conversion program (Example 4):

```
__numbertext__
^0 zero; 1 one; 2 two; 3 three; 4 four; 5 five; 6 six; 7 seven; 8 eight; 9 nine
10 ten; 11 eleven; 12 twelve; 13 thirteen; 15 fifteen; 18 eighteen; 1(\d) $1teen
20 twenty; 2(\d) twenty-$1; 30 thirty; 3(\d) thirty-$1; 40 forty; 4(\d) forty-$1
50 fifty; 5(\d) fifty-$1; 80 eighty; 8(\d) eighty-$1
(\d)0 $1ty
(\d)(\d) $1ty-$2
(\d)(00) $1 hundred

# separator function

```

4.2 Java implementation of the Soros interpreter[6]

```java
package org.numbertext;

import java.util.regex.Pattern;
import java.util.regex.Matcher;
import java.util.ArrayList;

public class Soros {
  private ArrayList<Pattern> patterns = new ArrayList<Pattern>();
  private ArrayList<String> values = new ArrayList<String>();
  private ArrayList<Boolean> begins = new ArrayList<Boolean>();
  private ArrayList<Boolean> ends = new ArrayList<Boolean>();

  private static String m = "\\\";#";
  private static String m2 = "$()|";
  private static String c = "\uE000\uE001\uE002\uE003";
  private static String c2 = "\uE004\uE005\uE006\uE007";
  private static String slash = "\uE000";
  private static String pipe = "\uE003";

  // pattern to recognize function calls in the replacement string

  private static Pattern func = Pattern.compile(translate(
      "(?:\\|?(?:\\$\\()+)?" +           // optional nested calls
      "(\\|?\\$\\(([^\\(\\)]*)\\))\\|?)" +   // inner call (2 subgroups)
      "(?:\\)+\\|?)?",                  // optional nested calls
      m2, c, "\\"));                    // \$, \(, \), \| -> \uE000..\uE003

  private boolean numbertext = false;

  public Soros(String source) {
    source = translate(source, m, c, "\\")    // \\, \", \;, \# -> \uE000..\uE003
      .replaceAll("(#[^\n]*)?(\n|$)", ";");   // remove comments
    if (source.indexOf("__numbertext__") > -1) {
      numbertext = true;
      source = source.replace("__numbertext__", "0+(0|[1-9]\\d*) $1\n");
    }
    Pattern p = Pattern.compile("^\\s*(\"[^\"]*\"|[^\\s]*)\\s*(.*[^\\s])?\\s*$");
    for (String s : source.split(";")) {
      Matcher sp = p.matcher(s);
      if (!s.equals("") && sp.matches()) {
          s = translate(sp.group(1).replaceFirst("^\"", "").replaceFirst("\"$",""),
            c.substring(1), m.substring(1), "");
          s = s.replace(slash, "\\\"); // -> \\, ", ;, #
```

---

6   This program is released under the free BSD license.

```
            String s2 = "";
            if (sp.group(2) != null) s2 = sp.group(2).replaceFirst("^\"",
"").replaceFirst("\"$","");
            s2 = translate(s2, m2, c2, "\\");   // \$, \(, \), \| -> \uE004..\uE007
            s2 = s2.replaceAll("(\\$\\d|\\))\\|\\$", "$1||\\$"); // $()|$() -> $()||$()
            s2 = translate(s2, c, m, "");        // \uE000..\uE003-> \, ", ;, #
